For up-and-in call option

- S(0) 2 < B
- pay-off at maturity is = (SCT)-K)+11 fms ZB3.

For down-and-in call option

- s(0)>B

- pay-off at maturity is = (S(DK) I I Ems = B}.

- up-and-out call:-

Our underlying asset is geometric Brownian motion ds(+)= > s(+)d++6s(+)dN(+)

Where W(+), 0 < t < T is a Brownian motion under the risu-neutral measure. P. consider a European call, expining at time T, with strike price K and up- and - out barrier B. we assume that K<B, otherwise the option must be known out (in order to be in the money and hence could only pay off zero). The solution to the Stochastic differential equation for the asset price is

$$S(t) = S(0)e^{6\widetilde{W}(t) + (n - \frac{1}{2}6^2) + } = S(0)e^{6\widetilde{W}(t)}$$

where $\widehat{W}(t) = \alpha t + \widehat{W}(t)$, and $\alpha = \frac{1}{6}(n - \frac{1}{2}6^2)$

we define M(T) = max W(+), so.

 $\max_{0 \le t \le T} s(t) = s(0)e^{6M(T)}$

The option knocusout if and only if sco) e (M(T) > B

The pay off of the option is = (SCT)-K) + 11 { score 6 MCT) < B?

$$V(\tau) = (s\omega)e^{6\widehat{W}(\tau)} - \kappa)^{+} 1 \{s\omega)e^{6\widehat{W}(\tau)} \le B\}.$$

$$= (s\omega)e^{6\widehat{W}(\tau)} - \kappa) 1 \{s\omega)e^{6\widehat{W}(\tau)} \ge \kappa\} 1 \{s\omega)e^{6\widehat{W}(\tau)} \le B\}.$$

$$= (s\omega)e^{6\widehat{W}(\tau)} - \kappa) 1 \{s\omega)e^{6\widehat{W}(\tau)} \ge \kappa, s\omega)e^{6\widehat{W}(\tau)} \le B\}.$$

$$= (s\omega)e^{6\widehat{W}(\tau)} - \kappa) 1 \{s\omega)e^{6\widehat{W}(\tau)} \ge \kappa, s\omega)e^{6\widehat{W}(\tau)} \le B\}.$$

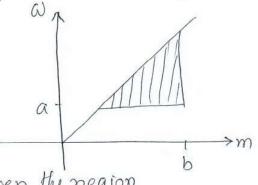

$$= (s\omega)e^{6\widehat{W}(\tau)} - \kappa) 1 \{s\omega)e^{6\widehat{W}(\tau)} \ge \kappa, s\omega)e^{6\widehat{W}(\tau)} \le B\}.$$

where $a = \frac{1}{6} \log \frac{k}{500}$ and $b = \frac{1}{6} \log \frac{B}{500}$.

The nisk-neutral price at time zero of the up-and-out call $V(0) = \mathbb{E} \left[e^{nT} V(T) \right]$

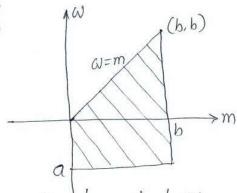

If azo, we must integrate over the negion

 $\{(m,\omega): a \leq \omega \leq m \leq b\}$

If a <0, we integrate over the negion

 $\{(m,\omega): \alpha \leq \omega \leq m, 0 \leq m \leq b\}$

In both cases the negion can be described as $\{(m,\omega); \alpha \leq \omega \leq b, \omega^{\dagger} \leq m \leq b\}$

Note that here SCO) ≤ B ⇒ b≥0.

We also evisume that
$$S(0) > 0$$
 so that a, b are finite.

$$V(0) = \int_{\omega=0}^{\infty} \int_{m=0}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{2(2m-\omega)}{T\sqrt{2\pi}T} e^{\alpha\omega - \frac{1}{2}\alpha^2T - \frac{1}{2T}(2m-\omega)^2} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{\alpha\omega - \frac{1}{2}\alpha^2T - \frac{1}{2T}(2m-\omega)^2} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{\alpha\omega - \frac{1}{2}\alpha^2T - \frac{1}{2T}(2m-\omega)^2} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{\alpha\omega - \frac{1}{2}\alpha^2T - \frac{1}{2T}(2m-\omega)^2} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{6\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{\alpha\omega} = -\int_{\alpha}^{\infty} e^{nT} \left(S(0) e^{2\omega} - K \right) \frac{1}{\sqrt{2\pi}T} e^{-nT} e^{nT} e^{nT}$$

$$= \frac{1}{\sqrt{2\pi}T} \int_{a}^{b} (s(0)e^{6\omega} - k) e^{-nT + \alpha\omega - \frac{1}{2}\alpha^{2}T} - \frac{1}{2T}\omega^{2} d\omega$$

$$- \frac{1}{\sqrt{2\pi}T} \int_{a}^{b} (s(0)e^{6\omega} - k) e^{-nT + \alpha\omega - \frac{1}{2}\alpha^{2}T} - \frac{1}{2T}(2b - \omega)^{2} d\omega$$

 $= S(0)I_1 - KI_2 - S(0)J_3 + KI_4$

Where
$$I_1 = \frac{1}{\sqrt{2\pi}T} \int_{\alpha}^{b} e^{6\omega - n\tau + \alpha\omega - \frac{1}{2}\alpha^2\tau - \frac{1}{2}\tau} d\omega$$

$$I_2 = \frac{1}{\sqrt{2\pi}T} \int_{\alpha}^{b} e^{\gamma t + \alpha \omega - \frac{1}{2}\alpha^2 t} - \frac{1}{2\tau} \omega^2 d\omega$$

$$J_{3} = \frac{1}{\sqrt{2711}} \int_{0}^{b} e^{6\omega - n\tau + \alpha\omega - \frac{1}{2}\alpha^{2}\tau - \frac{1}{2T}(2b - \omega)^{2}} d\omega$$

$$= \frac{1}{\sqrt{2\pi}T} \int_{0}^{b} e^{6\omega - 20T + \alpha\omega - \frac{1}{2}\alpha^{2}T - \frac{2b^{2}}{T} + \frac{2}{T}b\omega - \frac{1}{2T}\omega^{2}d\omega}$$

$$J_{A} = \frac{1}{\sqrt{2\pi}T} \int_{0}^{\pi} e^{nT + \alpha \omega} - \frac{1}{2}\alpha^{2}T - \frac{2}{7}b^{2} + \frac{2}{7}b\omega - \frac{1}{2T}\omega^{2} d\omega$$

Each of the integrals is of the form
$$J = \frac{1}{\sqrt{2\pi}T} \int_{a}^{b} e^{\beta + \gamma \omega} - \frac{1}{2T} \omega^{2} d\omega = \frac{1}{\sqrt{2\pi}T} \int_{a}^{b} e^{-\frac{1}{2T}(\omega - \vartheta T)^{2} + \frac{1}{2}\vartheta^{2}T + \beta} d\omega$$

Let
$$y = \frac{\Omega - \gamma T}{\sqrt{T}}$$
, then

$$I = e^{\frac{1}{2}y^{2}T + B} \frac{1}{\sqrt{2\pi}} \int_{-\frac{1}{2}\sqrt{T}}^{\sqrt{T}} e^{\frac{1}{2}y^{2}} dy$$

$$= e^{\frac{1}{2}y^{2}T + B} \left[N\left(\frac{b - \gamma T}{\sqrt{T}}\right) - N\left(\frac{a - \gamma T}{\sqrt{T}}\right) \right]$$

$$= e^{\frac{1}{2}y^{2}T + B} \left[N\left(\frac{-a + \gamma T}{\sqrt{T}}\right) - N\left(\frac{-b + \gamma T}{\sqrt{T}}\right) \right]$$

$$= e^{\frac{1}{2}y^{2}T + B} \left[N\left(\frac{-a + \gamma T}{\sqrt{T}}\right) - N\left(\frac{-b + \gamma T}{\sqrt{T}}\right) \right]$$

$$= e^{\frac{1}{2}y^{2}T + B} \left[N\left(\frac{1}{6\sqrt{T}} \left[\log \frac{s(a)}{K} + \gamma 6T\right] - N\left(\frac{1}{6\sqrt{T}} \left[\log \frac{s(a)}{B} + \gamma 6T\right]\right) \right]$$

Set $S_{+}(T, s) = \frac{1}{6\sqrt{T}} \left[\log s + (n \pm \frac{1}{2}c^{2})T\right]$

For J_{1} , $B = -nT - \frac{1}{2}a^{2}T$, $\gamma = 6 + \alpha$, so $\frac{1}{2}y^{2}T + B = \frac{1}{2}T(a + 6)^{2} - nT - \frac{1}{2}a^{2}T$

$$= \frac{1}{2}a^{2}T + \frac{1}{2}c^{2}T + 6\alpha T - nT - \frac{1}{2}a^{2}T = \left(\frac{1}{2}a^{2}C - n\right)T + T6\alpha$$

$$= (\frac{1}{2}c^{2} - n)T + T(n - \frac{1}{2}c^{2}) = 0$$

and $\gamma 6 = nD \left(6 + \alpha\right) 6 = 6^{2} + \alpha 6 = a + 6^{2} + (n - \frac{1}{2}6^{2})$

$$= n + \frac{1}{2}c^{2}$$

Therefore $J_{1} = N\left(S_{+}(T, \frac{S(a)}{K})\right) - N\left(S_{+}(T, \frac{S(a)}{B})\right)$

$$I_2 = \bar{e}^{\text{pot}} \left[N\left(S_{-}\left(T, \frac{S(0)}{K}\right)\right) - N\left(S_{-}\left(T, \frac{S(0)}{B}\right)\right) \right]$$

$$I_3 = \left(\frac{S(0)}{B}\right)^{\frac{-2n}{6^2}-1} \left[N\left(S_+\left(T, \frac{B^2}{k s(0)}\right)\right) - N\left(S_+\left(T, \frac{B}{s(0)}\right)\right)\right]$$

Finally for J_4 , we have $B = -nT - \frac{1}{2}\alpha^2T - \frac{2b^2}{T}$ and

$$\hat{v} = \alpha + \frac{2b}{7}, so$$

$$\frac{-2m}{62} + 1$$

$$\frac{1}{2} \hat{v}^2 + B = -m + \log \left(\frac{S(0)}{B}\right)^{\frac{2m}{62}} + 1$$

$$\hat{v} = (m - \frac{1}{2} 6^2) + \log \left(\frac{S(0)}{B}\right)^{\frac{2m}{62}} + 1$$

Therefore
$$T_{4} = e^{pT} \left(\frac{S(0)}{B} \right)^{\frac{2p}{62} + 1} \left[N(S_{-}(T, \frac{B^{2}}{KS(0)})) - N(S_{-}(T, \frac{B}{S(0)})) \right]$$

Putting all this together, under the assumption o< sco) ≤ B, we have the up-and-out call price formulla.

$$V(0) = S(0) \left[N(S_{+}(T, \frac{S(0)}{K})) - N(S_{+}(T, \frac{S(0)}{B})) \right]$$

$$- e^{nT} K \left[N(S_{-}(T, \frac{S(0)}{K})) - N(S_{-}(T, \frac{S(0)}{B})) \right]$$

$$- B \left(\frac{S(0)}{B} \right)^{\frac{2n}{62}} \left[N(S_{+}(T, \frac{B^{2}}{KS(0)})) - N(S_{+}(T, \frac{B}{S(0)})) \right]$$

$$+ e^{nT} K \left(\frac{S(0)}{B} \right)^{\frac{2n}{62}+1} \left[N(S_{-}(T, \frac{B^{2}}{KS(0)})) - N(S_{-}(T, \frac{B}{S(0)})) \right]$$

Theorem: Let V(t,x) denote the price at time t of the up-and-out call under the assumption that the call has not knocked out proon to time to and S(t) = x. Then V(t,x) satisfies the Black-Scholes-Menton partial differential equation

the boundary conditions

 $V(1,\infty) = 0$; 0 \(\text{1} \) V(1,B) = 0; 0 \(\text{1} \)

 $v(T,x) = (x-K)^+, 0 \le x \le B.$

Let us begin with an initial asset price S(0) ∈ (0,B) and

 $V(T) = (S(0) e^{6 \hat{W}(T)} - K) 1 \{ \hat{W}(T) \ge k, \hat{M}(T) \le b \}$

Where $\hat{W}(t) = \alpha t + \hat{W}(t)$ & $\hat{M}(T) = \max_{0 \le t \le T} \hat{W}(t)$

The price of the option at time t is given by the nisk-neutral pricing formula

 $V(t) = \mathbb{E}\left[e^{n(\tau-t)}V(\tau)|\mathcal{F}(t)\right], 0 \leq t \leq T$

Note that for set

 $\widehat{\mathbb{E}}\left[V(t)e^{nt}|f(s)\right] = \widehat{\mathbb{E}}\left[\widehat{\mathbb{E}}\left[e^{nT}V(T)|f(t)\right]|f(s)\right]$

 $= \widetilde{\mathbb{E}}\left[\widetilde{e}^{nT}V(\tau) \middle| \widetilde{\mathcal{T}}(s)\right] = \widetilde{e}^{ns}V(s)$

Therefore $\bar{e}^{nt}V(t)$ is a martingale.

By the Markov property V(+) = 2 (+, S(+)).

Define Let 9= inf { + 20 | 5(+) = B}.

Thun $e^{n(4\Lambda g)}V(4\Lambda g) = \begin{cases} e^{nt}V(t) & \text{if } 0 \leq t \leq g \\ e^{ng}V(g) & \text{if } g < t \leq T. \end{cases}$

we have $e^{pt} u(t, s(t))$ in a p-mantingale. The optional sampling theorem asserts that the stop process $e^{p(tAS)} u(tAS, s(tAS))$, ostst

is a mantingale under P.

compute the differential

 $d(\bar{e}^{nt}v(t,s(t))) = \bar{e}^{nt}[-nv(t,s(t))dt + v_t(t,s(t))dt + v_x(t,s(t))ds(t) + v_x(t,s(t))ds(t)]$

 $= e^{nt} \left[-nv(t,s(t)) + v_t(t,s(t)) + ns(t)v_x(t,s(t)) + v_t(t,s(t)) \right] dt$

tent 6s(t) vx(t,s(t))dw(t).

The dt term must be zero for $0 \le t \le 8$. But since (t,s(t)) can reach any point in $\{(t,x):0 \le t \le T,0 \le x \le B\}$ before the option knocks out. The B-s-M-equation must hold for every $t \in [0,T)$ and $x \in [0,B]$.

Remonu: setting dt temm eaual to zeno, acobtain $d(\bar{e}^{pt}v(t,s(t)) = \bar{e}^{pt}6s(t)v_{x}(t,s(t))d\tilde{w}(t)$

The discount value of a postfolio that each time & holds

 $\Delta(t)$ shares & the underlying asset is given by $d(\bar{e}^{nt}X(t)) = \bar{e}^{nt} 6S(t) \Delta(t) d\tilde{w}(t)$

At least theometically, if an agent begins with a shoot position in the up-and-out call and with initial capital x(0) = v(0, s(0)), the usual delta-hedging formula

 $2(t) = v_{2}(t,s(t))$ will cause her portfolio value x(t) to track the option value v(t,s(t)) up to time $g(t) = v_{2}(t,s(t))$ up to time $g(t) = v_{2}(t,s(t))$ up to expiration t, whichever comes first.

Lookback Options:
An option whose fayoff is based on the moximum on minimum of the underlying asset price attains over some interval of time prior to expination is called a lookback option. Examples $V(T) = \max\left[\max_{\xi \in T} S(t) - K, 0\right], V(T) = \max\left[K - \min_{\xi \in T} S(t), 0\right], V(T) = S(T) - \min_{\xi \in T} S(t).$ Here we consider floating strike lookback option. The payoff of this option is given by V(T) = Y(T) - S(T), at expination time T, where $S(t) = S(0)e^{6\hat{W}(t)}$, $\hat{W}(t) = \alpha t + \hat{W}(t)$, $\alpha = \frac{1}{6}(n - \frac{1}{2}6^2)$ with $\hat{M}(t) = \max_{0 \le u \le t} \hat{W}(u)$ and $Y(t) = \max_{0 \le u \le t} S(t) = S(0)e^{6\hat{W}(t)}$

 $S(t) = ns(t) dt + 6s(t) d\tilde{W}(t), \tilde{W}(t)$ is a Bnownran motion under risk-neutral measure \tilde{P} .

$$S(t) = e^{(n - \frac{1}{2}6^2)t} + 6 \widetilde{W}(t)$$
